

Stakeholders / Actors: Customer, Bank Employee, Loan Officer, Bank Manager, System Admin, Auditor

Req ID	Type	Description	Priority	Acceptance Criteria	Rationale
FR-001	Functional	Customers should be able to log in securely and view their account details and current balance at any time.	High	Pass: Balance and account details load within 2 seconds of login. Fail: Wrong balance shown, or login succeeds without valid credentials.	This is the core reason customers open the app, so it has to be fast and always correct.
FR-002	Functional	Customers need to deposit or withdraw money from their account, with the balance updating immediately.	High	Pass: Balance reflects the deposit/withdrawal instantly, and a confirmation is shown. Fail: Balance is delayed, incorrect, or no confirmation is given.	Money movement is the most basic banking action, so it can't be slow or unreliable.
FR-003	Functional	Customers should be able to transfer money from their account to another account within the bank.	High	Pass: Transfer completes and both sender and receiver balances update correctly. Fail: Money leaves one account without arriving in the other.	A failed or duplicated transfer directly costs customers money and trust.
FR-004	Functional	Customers can apply for a loan online, and loan officers can review, approve, or reject the request.	Medium	Pass: Application is submitted with a reference ID, and officer sees it in their queue. Fail: Application disappears or officer cannot action it.	Loans are a key product, but the process happens over days, so it's less time-critical than transactions.
FR-005	Functional	Customers can view a list of their past transactions, including deposits, withdrawals, and transfers.	Medium	Pass: All transactions from the last 12 months are listed with correct amounts and dates. Fail: Transactions are missing or shown out of order.	Customers rely on this to catch errors or fraud, so it needs to be complete and accurate.
NFR-001	Security	All sensitive data, such as passwords and account information, must be encrypted, and access must be controlled by user role.	High	Pass: Data is encrypted at rest and in transit; roles only see permitted data. Fail: Sensitive data is readable in plain text, or a role can access data it shouldn't.	A bank is a high-value target, so weak access control or unencrypted data is a serious risk.
NFR-002	Performance	The system should respond to common actions, like login or balance checks, within 2-3 seconds under normal load.	Medium	Pass: 95% of requests complete within 3 seconds under expected load. Fail: Response times regularly exceed 3 seconds.	Slow response times frustrate customers and make the bank feel unreliable, even if the data is correct.
